# Assignment Project Exam Help

Suppose you have an alphabet consisting of  $d$  symbols. Strings are just sequences of these symbols.

<https://tutorcs.com>

### Problem

Determine whether a string  $B = b_0b_1 \dots b_{m-1}$  (the *pattern*) appears as a (contiguous) substring of a much longer string  $A = a_0a_1 \dots a_{n-1}$  (the *text*).

WeChat: estutorcs

## String matching problem

# Assignment Project Exam Help

Attempt 1

The “naïve” algorithm for string matching is as follows: for every position  $i$  in  $A$ , check  $a_i \dots a_{i+m-1}$  against  $B$  character-by-character.

Even with early exit, this runs in  $O(mn)$  time in the worst case.

<https://tutorcs.com>  
WeChat: cstutorcs

Question

Can we do better?

# Assignment Project Exam Help

4. Puzzle

## String matching with hashing

Assignment Project Exam Help

- We now show how hashing can be combined with recursion to produce an efficient string matching algorithm.

- We compute a hash value for the string  $B = b_0 b_1 b_2 \dots b_{m-1}$  in the following way.

- First, map each symbol to a corresponding integer  $i \in \{0, 1, 2, \dots, d-1\}$  so as to identify each string with a sequence of these integers.

- Hereafter, when we refer to an integer  $a_i$  or  $b_i$ , we really mean the ID of the symbol  $a_i$  or  $b_i$ .

## Polynomial rolling hash

- We can therefore identify  $B$  with a sequence of IDs  $\langle b_0, b_1, b_2, \dots, b_{m-1} \rangle$ , each between 0 and  $d-1$  inclusive. Viewing these IDs as digits in base  $d$ , we can construct a corresponding integer

$$h(B) = h(b_0 b_1 b_2 \dots b_{m-1}) = d^{m-1} b_0 + d^{m-2} b_1 + \dots + d \cdot b_{m-2} + b_{m-1}.$$

- This can be evaluated efficiently using Horner's rule:

$$h(B) = b_{m-1} + d(b_{m-2} + d(b_{m-3} + d(b_{m-4} + \dots + d(b_1 + d \cdot b_0) \dots))),$$

requiring only  $m-1$  additions and  $m-1$  multiplications.

- Next we choose a large prime number  $p$  and define the hash value of  $B$  as  $H(B) = h(B) \bmod p$ .

# Assignment Project Exam Help

- Recall that  $A = a_0a_1a_2a_3 \dots a_{s-1}a_s a_{s+1} \dots a_{s+m-1} \dots a_{n-1}$  where  $n \gg m$ .

- We want to find efficiently all  $s$  such that the string of length  $m$  of the form  $a_s a_{s+1} \dots a_{s+m-1}$  and string  $b_0 b_1 \dots b_{m-1}$  are equal.

- For each contiguous substring  $A_s = a_s a_{s+1} \dots a_{s+m-1}$  of string  $A$  we also compute its hash value as

$$H(A_s) = d^{m-1}a_s + d^{m-2}a_{s+1} + \dots + d^1a_{s+m-2} + a_{s+m-1} \bmod p.$$

## Polynomial rolling hash

- We can now compare the hash values  $H(B)$  and  $H(A_s)$

- If they disagree, we know that there is no match.

- If they agree, there might be a match. To confirm this, we'll check it character-by-character.

- There are  $O(n)$  substrings  $A_s$  to check. If we compute each hash value  $H(A_s)$  in  $O(m)$  time, this is no better than the naïve algorithm.

- This is where recursion comes into play: we do not have to compute the hash value  $H(A_{s+1})$  "from scratch". Instead, we can compute it efficiently from the previous hash value  $H(A_s)$ .

## Assignment Project Exam Help

- Recall that  $A_s = a_s a_{s+1} \dots a_{s+m-1}$ , so

$$H(A_s) = d^{m-1}a_s + d^{m-2}a_{s+1} + \dots + a_{s+m-1} \bmod p.$$

<https://tutorcs.com>

- Multiplying both sides by  $d$  gives

$$\begin{aligned} d \cdot H(A_s) &= d^m a_s + d^{m-1} a_{s+1} + \dots + d^1 a_{s+m-1} \\ &= d^m a_s + (d^{m-1} a_{s+1} + \dots + d^1 a_{s+m-1} + a_{s+m}) - a_{s+m} \\ &= d^m a_s + H(A_{s+1}) - a_{s+m} \bmod p, \end{aligned}$$

since  $A_{s+1} = a_{s+1} \dots a_{s+m-1} a_{s+m}$ .

# Assignment Project Exam Help

- Rearranging the last equation, we have

$$H(A_{s+1}) = d \cdot H(A_s) - d^m a_s + a_{s+m} \bmod p.$$

<https://tutorcs.com>

- Thus we can compute  $H(A_{s+1})$  from  $H(A_s)$  in constant time.

Note

WeChat: cstutorcs

When implementing this, we need to make sure that the intermediate values are not too large. In particular, we need to choose  $p$  such that  $(d + 1)p$  fits in a single register. This is in conflict with the desired to choose large primes for better hashing.

## Assignment Project Exam Help

Algorithm

1. First compute  $H(B)$  and  $H(A_0)$  in  $O(m)$  time using Horner's rule.

<https://tutorcs.com>

2. Then compute the  $O(n)$  subsequent values of  $H(A_s)$  for  $s > 0$  each in constant time using the recurrence above.

WeChat: cstutorcs

3. Compare  $H(A_s)$  with  $H(B)$ , and if they are equal then confirm the potential match by checking the strings  $A_s$  and  $B$  character-by-character.

# Assignment Project Exam Help

- Since  $p$  was chosen large, the false positives (where  $H(A_s) = H(B)$  but  $A_s \neq B$ ) are very unlikely, which makes the algorithm run fast in the average case.

<https://tutorcs.com>

- However, as always when we use hashing, we cannot achieve useful bounds for the worst case performance.

WeChat: cstutorcs

- So we now look for algorithms whose worst case performance is guaranteed to be linear.

## String matching with finite automata

- A string matching finite automaton for a pattern  $B$  of length  $m$  has:

- $m + 1$  many states  $0, 1, \dots, m$ , which correspond to the number of characters matched thus far, and

<https://tutorcs.com>

- a transition function  $\delta(k, a)$ , where  $0 \leq k \leq m$  and  $a \in \mathcal{S}$ .

[WeChat: cstutorcs](#)

- Suppose that the last  $k$  characters of the text  $A$  match the first  $k$  characters of the pattern  $B$ , and that  $a$  is the next character in the text. Then  $\delta(k, a)$  is the new state after character  $a$  is read, i.e. the largest  $k'$  so that the last  $k'$  characters of  $A$  (ending at the new character  $c$ ) match the first  $k'$  characters of  $B$ .

## String matching with finite automata

Assignment Project Exam Help

As an example, consider the string  $B = xyxyxz$ . The table defining  $\delta(k, a)$  would then be as follows:

$k$	matched	x	y	z
0		1	0	0
1	x	1	2	0
2	xy	3	0	0
3	xyx	1	4	0
4	xyxy	5	0	0
5	xyxyx	1	4	6
6	xyxyxz	7	0	0
7	xyxyxzx	1	2	0

# String matching with finite automata

This table can be visualised as a state transition diagram. From each state  $k$ , we draw an arrow to  $k'$ ,  $a$  for each character  $a$  that could be encountered next. Arrows pointing to state 0 have been omitted for clarity.

<https://tutorcs.com>

$B = xyxyxz$

WeChat: estutorcs

# Assignment Project Exam Help

- How do we compute the transition function  $\delta$ , i.e., how do we fill the table?
- Let  $B_k = b_0 \dots b_{k-1}$  denote a prefix of length  $k$  of the string  $B$ .
- Being at state  $k$  means that so far we have matched the prefix  $B_k$ .
- If we now see an input character  $a$ , then  $\delta(k, a)$  is the largest  $\ell$  such that the prefix  $B_\ell$  of string  $B$  is a suffix of the string  $B_k a$ .

<https://tutores.com>

WeChat: cstutorcs

# String matching with finite automata

## Question

How do we find  $\delta(\ell, a)$ , the largest  $\ell$  such that  $B_\ell$  is a suffix of  $B_k a$ ?

- If  $a$  happens to match with  $b_k$ , i.e.  $B_k a = B_{k+1}$ , then  $\ell = k + 1$  and so  $\delta(k, a) = k + 1$ .
- But what if  $a \neq b_k$ ? Then we can't extend our match from length  $k$  to  $k + 1$ .
- We'd like to extend some shorter match instead.
- Any other candidates to be extended must be both a proper suffix of  $B_k$  and a prefix of  $B$ .

## The failure function

# Assignment Project Exam Help

### Definition

Let  $\pi(k)$  be the largest integer  $\ell$  such that the prefix  $B_\ell$  of  $B$  is a proper suffix of  $B_k$ .

$B_\ell$  is therefore the longest substring which appears at both the start and the end of  $B_k$  (allowing partial but not total overlap).

We will refer to  $\pi$  as the *failure function*.

## The failure function

The transition function  $\delta(k, a)$  is closely related to this failure function.

# Assignment Project Exam Help

- If  $a = b_k$ , then  $\delta(k, a) = k + 1$ .

<https://tutorcs.com>

- Otherwise, we look to extend a shorter match. The next candidate has length  $\pi(k)$ , so we check whether  $a = b_{\pi(k)}$  and if so we have  $\delta(k, a) = \pi(k) + 1$ .

WeChat: cstutorcs

- Otherwise, the next candidate has length  $\pi(\pi(k))$  (why?) and so on.

We will describe the algorithm and complete the analysis entirely in terms of the failure function.

## The failure function

# Assignment Project Exam Help

- Our first step is to solve the value of the failure function for each index of the pattern  $B$ .

- We will do this recursively using dynamic programming.

- Naturally, the subproblems are the  $\pi(k)$  values for each  $1 \leq k \leq n$ , and the base case is  $\pi(1) = 0$ .

- Suppose we have solved  $\pi(1), \dots, \pi(k)$ . How do we find  $\pi(k+1)$ ?

## The failure function

- Recall that  $B_{\pi(k)} = b_0 \dots b_{\pi(k)-1}$  is the longest prefix of  $B$  which is a proper suffix of  $B_k = b_0 \dots b_{k-1}$ .

- To compute  $\pi(k+1)$ , we first try to extend this match, by checking whether  $b_k = b_{\pi(k)}$ .

- If true, then  $\pi(k+1) = \pi(k) + 1$ .

- If false, then we cannot extend  $B_{\pi(k)}$ . What's the next longest prefix of  $B$  which is a proper suffix of  $B_k$ ?

- It's  $B_{\pi(\pi(k))}$ ! So we check whether  $b_k = b_{\pi(\pi(k))}$ .

- If true, then  $\pi(k+1) = \pi(\pi(k)) + 1$ .

- If false, check whether  $b_k = b_{\pi(\pi(\pi(k)))} \dots$

## The failure function

```
1: function COMPUTE-FAILURE-FUNCTION( $B$ )
```

```
2:    $m \leftarrow |B|$ 
```

```
3:   let  $\pi[1..m]$  be a new array, and  $\pi[1] \leftarrow 0$ 
```

```
4:    $\ell \leftarrow 0$ 
```

```
5:   for  $k = 1$  to  $m - 1$  do
```

```
6:     while  $\ell \geq 0$  do
```

```
7:       if  $b_k = b_\ell$  then
```

```
8:          $\ell \leftarrow \ell + 1$ 
```

```
9:         break
```

```
10:      end if
```

```
11:      if  $\ell > 0$  then
```

```
12:         $\ell \leftarrow \pi[\ell]$ 
```

```
13:      else
```

```
14:        break
```

```
15:      end if
```

```
16:    end while
```

```
17:     $\pi[k + 1] \leftarrow \ell$ 
```

```
18:  end for
```

```
19:  return  $\pi$ 
```

```
20: end function
```

# The Knuth-Morris-Pratt algorithm

- What is the complexity of this algorithm? There are  $O(m)$  values of  $k$ , and for each we might try several values  $\ell$ ; is this  $O(m^2)$ ?

- No! It is actually linear, i.e.  $O(m)$ .

- Maintain two pointers: the left pointer at  $k - 1 - \ell$  (the start point of the match we are trying to extend) and the right pointer at  $k$ .

- After each 'step' of the algorithm (i.e. each comparison between  $b_k$  and  $b_\ell$ ), exactly one of these two pointers is moved forwards.

- Each can take up to  $m$  values, so the total number of steps is  $O(m)$ . This is an example of *amortisation*.

# The Knuth-Morris-Pratt algorithm

- We can now do our search for the pattern  $B$  in the text  $A$ .

- Suppose  $B_s$  is the longest prefix of  $B$  which is a suffix of  $A_i = a_0 \dots a_{i-1}$ .

- To answer the same question for  $A_{i+1}$ , we begin by checking whether  $a_i = b_s$ .

- If true, then the answer for  $A_{i+1}$  is  $s + 1$

- If false, check whether  $a_i = b_{\pi(s)} \dots$

- If the answer for any  $A_i$  is  $m$ , we have a match!

- Reset to state  $\pi(m)$  to detect any overlapping full matches.

- By the same two pointer argument, the time complexity is  $O(n)$ .

## Looking for imperfect matches

Sometimes we are not interested in finding just the perfect matches, but also in matches that might have a few errors, such as a few insertions, deletions and replacements.

Problem

**Instance:** a text

$$A = a_0 a_1 a_2 a_3 \dots a_s a_{s+1} \dots a_{s+m-1} \dots a_{n-1},$$

a pattern  $B = b_0 b_1 b_2 \dots b_{m-1}$  where  $m \ll n$ , and an integer  $k \ll m$ .

**Task:** find all matches for  $B$  in  $A$  which have up to  $k$  errors.

## Looking for imperfect matches

# Assignment Project Exam Help

### Solution Outline

Split  $B$  into  $k + 1$  substrings of (approximately) equal length. Within any match in  $A$  with at most  $k$  errors, at least one of these  $k + 1$  parts of  $B$  must be matched perfectly.

For each of the  $k + 1$  parts of  $B$ , we use the Knuth-Morris-Pratt algorithm to find all perfect matches in  $A$ .

Then for each of these matches, we test by brute force whether the remaining parts of  $B$  match sufficiently with the appropriate parts of  $A$ .
